6. Adjustment Procedures

6-(1) Main Amp. Center Voltage

1. Before tuning on the power, set semi-fixed resistors R305 (L channel) and R306 (R channel) of the drive amplifier and regulated power voltage amplifier circuit

board (TXX-183B-1) to the center position (refer to Fig. 12).

 Five minutes after the power is turned on, adjust semifixed resistors R305 and R306 so that the voltage between the test points of the power circuit board becomes ±10 mV or less.

L channel: Measure the voltage between test point 19 and test point 22 (ground).

R channel: Measure the voltage between test point 7 and test point 4 (ground).

The measurements can also be performed at the speaker terminals if the relay is operating normally.

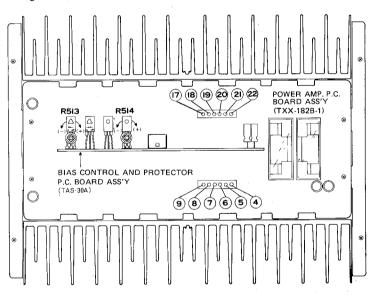

Fig. 13

6-(2) Main Amp. Idling Current

- 1. Before turning on the power, turn semi-fixed resistors, R513 (L channel) and R514 (R channel) of the bias control and protection circuit board, fully counterclockwise (refer to Fig. 13).
- 2. After turning the power on, adjust R513 and R514 and so that the voltage between the test points of the power amplifier (see Fig. 13) is within the range 40 mV 60 mV.

L channel: Measure the voltage between test points 17, 18, 20 and 21, and test point 19 (center point).

R channel: Measure the voltage between test points 5, 6, 8 and 9, and test point 7 (center point).

3. About 10 minutes after the power is turned on with the heat sink hot enough, readjust R513 and R514 so that the voltage between the test points becomes 50 mV. Then, confirm that no voltage variation is observed after the heat sink temperature increases further.

Note: Be sure to perform the measurement with the probes and cabinet of the measuring equipment separated from the ground terminals of A-X9 or of other measuring equipment.

The A-X9 may be damaged if this is neglected.

7. Servicing Procedures

7-(1) Main Amp.

Troubleshooting and servicing for damaged power transistors are most difficult with this unit.

These are explained here.

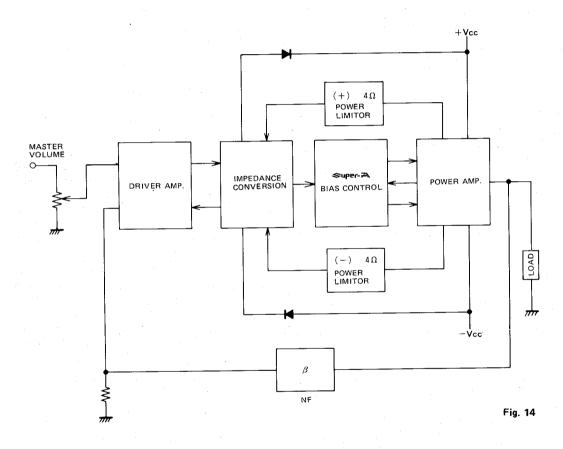

The power amplifier of A-X9 has a configuration shown in Fig. 14. Servicing should be performed with consideration paid for separation of the stages.

Standard simplified servicing methods must be avoided when repairing the Super A amp. Turning on the power immediately after replacing the power transistors because they have been damaged or replacing the parts for the right channel with those for the left channel or vice versa (this

method is often employed when repairing a stereo circuit) must be avoided strictly.

Note: Servicing procedures for the left channel are given here together with those necessary for the right channel. However, similar servicing should be performed for both channels at the same time so that the performance of the left and right channels is the same.

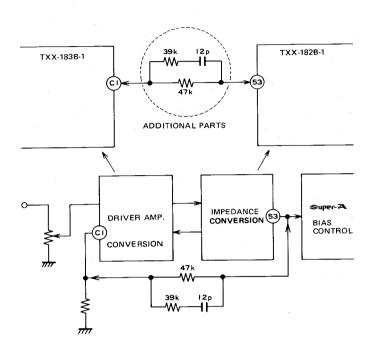

If this is neglected, the parts of the channel which was normal may be damaged.

1. Troubleshooting

- 1) Separate the power amplification stage from the bias stage to check the stage with trouble.
 - (1) Remove one of the leads of resistors R437 (560 Ω) and R439 (47 Ω) to disconnect the bias stage from the power amplification stage.
 - (2) Connect the bases of X421 (2SC2229) and X423 (2SA949) through a resistor of approx. 1 $k\Omega$ so that DC bias current is not applied to the first stage of the power amplifier.
 - (3) Remove the power limitters X417 (2SC458) and X419 (2SA1029).
 - (4) Remove the overcurrent prevention diodes D401 and D403 (1SS81).
 - (5) Remove the 3-pin connector (3 pins 1, 2, 3 on the power amplifier circuit board TXX-182B-1) which is employed to provide feedback from the output stage to the first stage.

- (6) Remove one of the wires (the wire between S and S' on the circuit board TXX-182B-1) by which the output voltage is transmitted from the output center point to the Super A bias circuit.
 - Note: For the right channel, the wire with the same function as that between S and S' is jumper wire W417.
- (7) Mount the external parts shown in Fig. 15 to allow feedback, and set Subsonic and Tone switches to the OFF positions.

Method to allow the negative feedback in the bias circuit

Fig. 15

- (8) Remove the 3-pin connector (the connector is in the wiring connecting 23, 24, 25 on power amplifier circuit board TXX-183B-1 with the B coil of the transformer) with which the ±B voltage is supplied to the power amplification stage. Set the power amplification stage in the non-operation stage.
- (9) Turn on the power. Measure the voltage between the collectors of X409 (2SA899) and X411 (2SC1904). Reduce the output volume to the minimum level to prevent an unnecessary input from being applied. Turn semi-fixed resistor R513 to adjust the bias current to check that the voltage variation is 3.5 - 4.7 V. If it is, the signal amplification circuit from the first stage to the Super A bias circuit is normal.

In this measurement an error of $0.2-0.3\,\mathrm{V}$ is allowable. However, if the error exceeds $0.5\,\mathrm{V}$, trouble exsists with the circuit.

As to polality, the X409 (2SA899) side is positive and the X411 (2SC1904) side is negative.

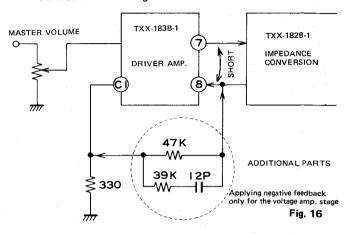

Be sure to fully turn R513 after the checking so that the measured voltage becomes minimum.

- If there is no trouble prior to the bias stage as described in 1-(9), repair the power amplification stage. For repairing, refer to "5. Repairing the power amplification stage".
- 3) If trouble exsists before the bias circuit output, perform repairing following the order of; Impedance conversion stage → Super A bias circuit stage as described in "2. Repairing the voltage amplification stage".

2. Repairing the voltage amplification stage

1) Prepare the additional parts to be mounted outside <refer to 1-1-(7)> and a wire to be employed for shorting.

Mount as shown in Fig. 16.

- 2) Remove the 7-pin connector (pins 10 16 of the power amplifier circuit board TXX-182B-1) connecting the voltage amplification stage with the impedance conversion stage first. (A value of 0 V should be otained by adjusting semi-fixed resistor R305.)
- Check if the offset voltage (the output voltage of the voltage amplification circuit TXX-183B-1 at pins 7 or 8) is correct.
- 4) Turn the output volume control to the maximum position and read the gain and the maximum output level at the points mentioned above.
 Gain → 43 dB ±1 dB
 - Maximum output level → Approx. 40 V rms
- 5) If the conditions in steps 3 and 4 are satisfied, this stage is normal.

3. Repairing the impedance conversion stage

- 1) Remove the shoring wire fitted in step 2-1. Refit the externally mounted parts for negative feedback to the original positions shown in 1-1-(7).
- Insert the connector which has been disconnected in step 2-2.
- Remove the connector Super A bias circuit board TAS-30A from the power amplifier circuit board TXX-182B-1
- 4) Check if the offset voltage can be properly adjusted at the output point (point 53 of TXX-182B-1) of the impedance conversion stage (0 V should be obtained by adjusting semi-fixed resistor R305).
- 5) Check the gain and maximum output voltage at the same test point in the same way as with the voltage amplification stage.

Note: Since no gain is available at the impedance conversion stage, the gain between the input and this stage is 43 dB.

(The maximum output level becomes approx. 38 – 40 V rms due to some loss.)

6) If the conditions in steps 4 and 5 are satisfied, operation between the input and this stage is normal.

4. Repairing the Super A bias circuit

- 1) Insert the Super A bias circuit board TAS-30A into the specified position.
- Repair the circuit until the conditions in 1-1-(9) become satisfactory.
- 3) Repairing hints
 - Check if a voltage 1.8 − 2 V is available between the collectors and emitters of X413 and X415 (2SC458) of the battery circuit.
 - Check if the emitter voltage of X509 (2SC458) is lower than its base voltage by $0.6-0.7~\rm{V}$.
 - Check if the emitter voltage of X511 (2SA1029) is higher than its base voltage by 0.6 - 0.7 V.
 - Check if the voltage between the emitter and base of X505 (2SA1029) is almost the same as that between the base and emitter of X509 (2SA1029).
 - Check if the voltage between the collector and emitter of X507 (2SC458) is almost the same as that between the base and emitter of X511 (2SC458).
 - Check if the regulated current circuit of X409 (2SA899) and X411 (2SC1904) correctly provides the regulated current of approx. 4 mA.

Note: If a voltage of approx. 4.8 V is present between the terminals of R419 and R421 (1.2 k), a current of approx. 4 mA is available at the emitters of X409 and X411.

 Check if the regulated current circuit of X501 (2SA899) and X411 (2SC1904) correctly provides the regulated current of approx. 8 mA.

Note: If a voltage of approx. 5 V is present between the terminals of R501 and R503 (680 Ω), the circuit is operated normally as above.

 Check if the Zener diode in the base bias circuit of the regulated power current transistor provides the correct voltage.

Note: Trouble cannot detected by merely checking the Zener diode resistance in the forward and backward directions, using a tester. Checking with a tester may not be effective to distinguish a usable Zener diode from a defective one (even the voltage is reduced by 30 — 40 percent).

- Check if Schottky diodes D503 and D505 are not open or short-circuited.
- Check if resistors R523 and R525 (47 Ω) are not open due to being burnt out.
- Check if a voltage variation of 0.6 0.8 V (VBE + 0.1 V) is obtained between the collector of X505 (2SA1029) and the emitter of X507 (2SC458) by turning semi-fixed resistor R513 for bias adjustment. If the voltage variation is not obtained, also check the resistor itself.

Be sure to fully turn the semi-fixed resistor counterclockwise after adjustment.

5. Repairing the power amplification stage

- Repairing this stage is not so difficult. However, if the repairing is not complete, the expensive output transistors may be damaged again. Repair taking care of the following points.
 - Is R455 (68 Ω 1/2 W) broken?
 - Is R455 (820 Ω 1/2 W) burnt out? Is it open?
 - Are R411 and R443 (47 Ω) burnt out? Are they open?
 - Are R437 (560 Ω) and R439 (47 Ω) burnt out? Are they open?

- 2) Before turning on the power be sure to confirm that the bases of X421 (2SC2229) and X243 (2SA949) are connected through a resistor of around 1 k Ω .
- 3) Checking when turning on the power
 - (1) Check that the voltage between the bases of X421 (2SC2229) and X423 (2SA949) and ground is 0 V using a voltmeter (tester) having a low internal resistance.
 - (2) Check if the voltage between the base/emitter of all transistors comprising the Darlington circuit and ground is 0 V using the same voltmeter as in (1).
- 4) Overall checking

After completion of repairing of each stage, put the checked sections back in their original states, except the power limitters and overcurrent prevension diodes.

Exercise care with the following.
 Is the bias circuit board connected?
 Is the resistor for idling current adjustment correctly set?

Are the resistors that were removed replaced?
Are the jumper wires that were removed replaced?
Are the parts that were externally mounted removed?
Are the connectors connected?

After confirming these points, turn on the power.

- (1) Adjust the idling current and offset voltage referring to the section "Adjustment procedure".
- (2) Check the maximum output voltage while the output level is gradually increased with the control with a load connected to the output terminals.
- (3) Perform the checking of 2. through an 8 Ω resistor.
- (4) Perform the checking of 2. through a 4 Ω resistor.
- (5) After replacing power limitters X417 (2SC458) and X419 (2SA1029) in their original state, check if the non-clip output with a 4 Ω resistor is less than 19 V at 1 kHz.
- (6) After replacing diodes D401 and D403 (1SS81) in their original state, check that operation is correct.

7-(2) Indicators

1. Indicator lamp circuit design

The circuit consists of 2 blocks; one comprises the 5 series connected lamps "POWER" — "TONE" and the other consists of the 7 series connected lamps "MUTING" — "MC". The lamps light with the regulated current from the 2 regulated current circuits with a common base circuit.

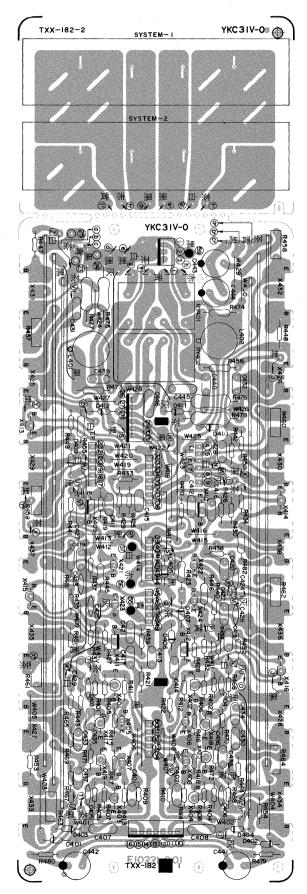

2. Defective lamp phenomena and troubleshooting If a lamp is defective, not only all the lamps in the same block but lamps in the other block may not light. Consequently, if other lamps which have been lighting do not light when a switch is operated, the lamp related with the switch is defective.

(Example: If other lamps which have been lighting do not light when the AUX switch is pressed, it means that the AUX lamp is defective.

For the same reason, if the POWER indicator lamp is defective, other lamps do not light even when the power switch is turned on.)

8. Printed Circuit Board Ass'y and Parts List

8-(1) TXX-182B Power Amp. and Speaker Connector P.C. Board Ass'y

① TXX-182B-1: Power Amp. P.C. Board Ass'y

② TXX-182-2: Speaker Connector

P.C. Board Ass'y

Note:

The specific symbols (未 黑 白 ... etc.) on a surface of above P.C. Board are actually unrelated to the repair service and are significant denotement in order to process the proper assembly of P.C. Board at the factory.

11.A-X9 Schematic Diagram (for U.S.A. and Canada)

(for U.S.A. and Canada)

How to utilize the circuit diagram

- 1. indicates positive B power supply
- 2. indicates negative B power supply.
- 3. indicates the signal path.
- 4. Voltage values measured with a tester (impedance 20 k Ω /V) in mode of "no signal" are indicated as below:

Example: 0.3 (unit:V)

-9.0 (unit : V)

5. When replacing the A marked parts, be sure to use the designated parts to ensure safety.

Relay

Fusible resistor

: Different in different areas.

See page 28.
